A Novel Composite Tube Design with Bend-Twist Coupling

SEAN ROHDE, PETER IFJU and BHAVANI SANKAR

ABSTRACT

A novel design of a composite circular tube possessing bend-twist coupling at the structural level is presented. When subjected to a bending moment the tube undergoes twisting in addition to bending. Conversely a torque results in bending in addition to rotation. This coupling causes the shear center of the cross section to be away from the center of the tube. An analytical model is proposed and closed-form equations for shear center distance are derived for both straight and tapered composite tubes. The results are verified by performing finite element analysis. Special tubes were fabricated and tested to measure the shear center distance. The agreement in results is excellent. It is found that the location of the shear center is independent of the shaft radius but proportional to the length of the tube.

1 INTRODUCTION

Tubular structures are an efficient design when it is necessary to carry the combined loading of bending and torsion. There are applications when a transverse force needs to be applied to a tubular lever eccentrically without resulting in twisting. Examples include golf clubs or robotic lifting arms. In circular tubes made of a homogeneous material the shear center is always at the center of the circular cross section. It is true for tubes made of an anisotropic material as long as the entire cross section is of the same material. By extension it is true for any laminated tube with any arbitrary laminate stacking sequence, as long as the lay-up remains the same along the entire circumference of the tube. Thus the only way the shear center can be moved in a tube is by using two different materials.

Sean Rohde, Peter Ifju, Bhavani Sankar, Department of Mechanical and Aerospace Engineering, University of Florida, P.O. Box 116250, Gainesville, Florida 32611, USA

Recently, Rohde et al. [1], [2], [3] have proposed a novel design for composite tubes which is intended to create a coupling effect between bending and twisting deformations. The design is described in detail in the experimental section. First we present a beam theory for an anisotropic composite tube subjected to combined bending and torsion to characterize the bend-twist coupling in the aforementioned tube by Rohde et al. The analytical results are verified using finite element analysis and experimental testing. A simple formula is derived for the shear center distance, distance of shear center from the axis of the tube. This can be used to optimize the design to achieve the desired shear center distance, as a larger shear center distance means a greater amount of bend-twist coupling.

Rao and Chan [4] have developed an analytical model for the analysis of laminated tubes subjected to both an axial force and a twisting moment. They modified the lamination theory to account for the ply stiffness of a differential element along the circumference of the tube using the appropriate transformation. Then the stiffness of the tube was obtained by integrating the stiffness around the circumference. In the present approach, suitable assumptions are made about the deformation of the tube and the shear stress distribution. This leads to an independent beam theory for composite tubes.

In the experimental section, a brief description of the design and construction of these shafts is detailed, including the unique problems that arose in their construction. The experimental set-up is detailed which explains the equipment constructed for locating the shear center. Many of the steps were repeated multiple times in order to reduce the measurement uncertainty.

2 ANALYTICAL MODEL

In this paper we give a brief description of the analytical model. The details can be found in [3]. Consider a thin-walled tube with the tube axis parallel to the $x$-axis. The mean radius of the tube is $R$ and the wall thickness $h<<R$. The tube is made of two anisotropic materials - top half is made of Material 1 and the bottom half is of Material 2. We assume that the tube is in a state of plane stress normal to the radial direction $n$ (see Figure 2) such that $\sigma_{nn} = \tau_{nr} = \tau_{nn} = 0$. Furthermore, we assume the hoop or
circumferential stress $\sigma_{\theta} = 0$. Thus the two significant stresses are the axial stress $\sigma_z$ and the shear stress $\tau_{xz}$. We assume that the tube deforms such that plane sections remain plane and normal to the tube axis as in Bernoulli-Euler beam theory. As will be seen later this assumption works well for the thin-walled, long tubes considered in this study. Then the displacement field can be written as

\[ u(x, y, z) = u_0(x) - y \frac{dv_0}{dx} - z \frac{dw_0}{dx} \]
\[ v(x, y, z) = v_0(x) \]
\[ w(x, y, z) = w_0(x) \] (1)

where $u_0$, $v_0$ and $w_0$ are the deflections of the beam axis. The axial strain takes the form

\[ \varepsilon_{zz} = \frac{\partial u}{\partial x} \]
\[ = \frac{\partial u_0}{\partial x} - y \frac{d^2 v_0}{dx^2} - z \frac{d^2 w_0}{dx^2} \]
\[ = \varepsilon_{zz} + y \kappa_y + z \kappa_z \] (2)

where $\kappa_y$ and $\kappa_z$ are the curvatures. We do not make any specific assumption about the rotation of the cross section except the average rotation of the cross-section about the $x$-axis is denoted by $\psi$. But we assume the shear stress is uniform and given by

\[ \tau_{xz} = \frac{T}{2\pi R^2 h} = \tau_0 \] (3)

where $T$ is the torque acting on a cross section. The constitutive relation for both materials can be written in the form [5]
\[
\begin{align*}
\begin{bmatrix}
\varepsilon_{xx} \\
\gamma_{ss}
\end{bmatrix} &= \begin{bmatrix}
\frac{1}{E_x} & \frac{\eta_{ss,x}}{E_x} \\
\frac{\eta_{ss}}{E_x} & \frac{1}{G_{ss}}
\end{bmatrix}
\begin{bmatrix}
\sigma_{xx} \\
\tau_{ss}
\end{bmatrix} = \begin{bmatrix}
\bar{S}_{11} & \bar{S}_{16} \\
\bar{S}_{16} & \bar{S}_{66}
\end{bmatrix}
\begin{bmatrix}
\sigma_{xx} \\
\tau_{ss}
\end{bmatrix} \\
\end{align*}
\]  

(4)

where \( E \) and \( G \) are Young's modulus and shear modulus, respectively, \( \eta \) is the coefficient of mutual influence of the material, and \( \bar{S}_g \) are the transformed compliance terms of the lamina. Then from (2), (3) and (4) we obtain

\[
\sigma_{xx} = E_x \varepsilon_{xx} - \eta_{ss,x} \tau_{ss} \\
= E_x (\varepsilon_{x0} + y \kappa_x + z \kappa_z) - \eta_{ss} \tau_0
\]  

(5)

The force and bending moment resultants are defined as

\[
(P, M_y, M_z) = \int_A \sigma_{xx} (1, z, -y) dA \\
= \int_0^{2\pi} \sigma_{xx} (1, R \sin \theta, -R \cos \theta) Rd\theta
\]  

(6)

where the integration is performed over the cross section of the tube. Substituting for \( \sigma_{xx} \) from (5) we obtain relations between the force and moment resultants and deformations [3]:

\[
\begin{bmatrix}
\bar{E}_x A & \frac{AR}{\pi} \Delta E_x \\
\frac{AR}{\pi} \Delta E_x & \bar{E}_x I
\end{bmatrix}
\begin{bmatrix}
\varepsilon_{x0} \\
\kappa_z
\end{bmatrix} = \begin{bmatrix}
P \\
M_y
\end{bmatrix} + \begin{bmatrix}
A \bar{\eta}_{ss,x} \\
2R^2 h \Delta \eta_{ss}
\end{bmatrix} \tau_0
\]  

(7)

\[
\bar{E}_x I \kappa_z = -M_z
\]

In the above equations \( \bar{E}_x \) is the average Young's modulus given by \( \bar{E}_x = (E_x^{(1)} + E_x^{(2)})/2 \), \( \Delta E_x \) is the difference in the Young's moduli, \( \Delta E_x = (E_x^{(1)} - E_x^{(2)}) \). Similarly \( \bar{\eta}_{ss,x} = (\eta_{ss,x}^{(1)} + \eta_{ss,x}^{(2)})/2 \) and \( \Delta \eta_{ss,x} = (\eta_{ss,x}^{(1)} - \eta_{ss,x}^{(2)}) \), \( A = 2\pi Rh \) is the cross sectional area and \( I \) is the second moment of inertia given by \( I = \pi R^2 h \). Equation (7) can be inverted to obtain
\[
\begin{align*}
\{\varepsilon_{z0}\} &= \frac{1}{K} \begin{bmatrix} -\frac{\Delta E_z}{\pi} & -\frac{AR}{\pi}\Delta E_z \\ \frac{AR}{\pi}\Delta E_z & \frac{AR}{\pi}\Delta E_z \end{bmatrix} \begin{bmatrix} P \\ M_y \end{bmatrix} + \begin{bmatrix} \bar{\eta}_{z,xx} / R \\ \Delta \eta_{z,zz} / \pi \end{bmatrix} \quad T
\end{align*}
\]

\[
\kappa_y = -M_z / E_x I
\]

(8)

where

\[
K = E_x^2 AI - \left(\frac{AR\Delta E_z}{\pi}\right)^2
\]

Thus one can calculate the deformations from the force and moment resultants. The deflections can be obtained by integrating the strains and curvatures. From equation (8) it is evident that a torque \( T \) can result in curvature \( \kappa_y \) causing deflection of the tube in the z-direction. It is interesting to note that the torque \( T \) does not cause curvature \( \kappa_y \) and this is due to symmetry of the cross section about the z-axis. The average unit angle of twist can be derived as

\[
\bar{\phi} = \bar{\eta}_{z,xx} / R \varepsilon_{z0} + \frac{\Delta \eta_{z,zz}}{\pi} \kappa_z + \frac{1}{R} \left[ \frac{\bar{\eta}_{z,xx}^2}{E_x} + \frac{1}{G_{zz}} \right] \tau_0
\]

(9)

where

\[
\frac{\bar{\eta}_{z,xx}^2}{E_x} = \frac{1}{2} \left( \frac{\bar{\eta}_{z,xx}^{(1)}}{E_x} \right)^2 + \frac{1}{2} \left( \frac{\bar{\eta}_{z,xx}^{(2)}}{E_x} \right)^2
\]

\[
\frac{1}{G_{zz}} = \frac{1}{2} \left( \frac{1}{G_{zz}^{(1)}} + \frac{1}{G_{zz}^{(2)}} \right)
\]

(10)

Again the details of the derivations can be found in [3].

Using eq. (8) one can express \( \varepsilon_{z0} \) and \( \kappa_z \) in eq. (9) in terms of force and moment resultants \( P, M_y \) and \( T \). Thus it is obvious that a bending moment \( M_y \) about the y-axis can cause twisting in the tube demonstrating the bend-twist coupling.

The present formulation is based on Euler-Bernoulli beam theory and hence the shear stresses due to transverse forces \( V_x \) and \( V_y \) are not accounted for. Only the shear stresses due to the torque are included. The transverse shear stresses can be recovered from \( \sigma_{zz}(x) \) using the equilibrium equation as in classical mechanics of materials. Integrating the equilibrium equation we obtain [3]

\[
\tau_{zz}(\theta) = \tau_{zz}(0) - \frac{V_y R^2 E_x^{(1)}}{E_x I} \sin \theta, \quad 0 < \theta < \pi
\]

\[
= \tau_{zz}(0) - \frac{V_y R^2 E_x^{(2)}}{E_x I} \sin \theta, \quad \pi < \theta < 2\pi
\]

(11)
3 APPLICATION TO FIBER COMPOSITE TUBES

3.1 Tube Made of an Anisotropic Material with Different Orientations

Recently Rohde et al. [1] have proposed a novel composite tube design which exhibits the bend-twist coupling described in the previously (see Figure 3). In this design two different lay-ups or fiber orientations are used for each half of the circular tube. Assume the tube is made of a unidirectional fiber composite. The fiber-angle is the angle between the fiber direction (1-direction) and the \( x \)-axis. It is assumed \( +\alpha \) for the top half of the tube (Material 1) and \( -\alpha \) for the bottom half (Material 2) as shown in Figure 3 and Figure 4.

![Figure 3. An isometric view of the composite tube showing different fiber orientations on the top and bottom halves.](image)

![Figure 4. The left figure shows the top half of the tube with fiber orientation \( +\alpha \). Right figure shows the bottom half (fiber angle \(-\alpha\) viewed from the top. Note the difference in the direction of circumferential direction (\( s \)-axis) in the two figures.](image)

The elastic constants in the \( x-s \) coordinate system can be obtained from the orthotropic engineering elastic constants \( E_1, E_2, G_{12} \) and \( \nu_{12} \) as follows [5]:
\[
\frac{1}{E_s} = \frac{1}{E_1} I^4 + \left(-\frac{2\nu_{12}}{E_1} + \frac{1}{G_{12}}\right) I^2 m^2 + \frac{1}{E_2} m^4
\]
\[
\frac{1}{G_{xx}} = 2 \left(\frac{2\nu_{12}}{E_1} + \frac{4\nu_{12}}{E_1} - \frac{1}{G_{12}}\right) I^2 m^2 + \frac{1}{G_{12}} \left(I^4 + m^4\right)
\]
\[
\eta_{s,xx} = \left(\frac{2\nu_{12}}{E_1} + \frac{1}{G_{12}}\right) I^3 m + \left(-\frac{2\nu_{12}}{E_1} - \frac{2}{G_{12}}\right) I m^3
\]
\[
l = \cos \alpha, \quad m = \sin \alpha
\]

It is obvious from the above relations that for the present example

\[ E_x^{(1)} = E_x^{(2)} = \bar{E}_x, \quad \Delta E_x = 0, \quad G_{xx} = G_{xx}^{(2)} = \bar{G}_{xx}, \quad \Delta G_{xx} = 0 \]

\[ \eta_{s,xx}^{(1)} = -\eta_{s,xx}^{(2)}, \quad \bar{\eta}_{s,xx} = 0, \quad \Delta \eta_{s,xx} = 2\eta_{s,xx}, \quad \frac{\eta_{s,xx}^2}{\bar{E}_x} = \left(\frac{\eta_{s,xx}^{(1)}}{\bar{E}_x}\right) \]

Then equations (7) and (9) can be simplified as

\[
\bar{E}_s A \varepsilon_{x_0} = P
\]
\[
\bar{E}_s I \kappa_x = M_y + 4R^2 h \eta_{s,xx} \tau_0
\]
\[
\bar{E}_s I \kappa_y = -M_z
\]
\[
\bar{\phi} = \frac{2\eta_{s,xx}^{(1)}}{\pi} \kappa_x + \frac{1}{R} \left[ \frac{1}{\bar{G}_{xx}} - \frac{\left(\eta_{s,xx}^{(1)}\right)^2}{\bar{E}_x} \right] \tau_0
\]

From the above relations (2\textsuperscript{nd} and 4\textsuperscript{th} equations) one can note the coupling between the bending moment \(M_y\) and the torque \(T\). The two relevant equations can be written as

\[
\kappa_x = \frac{M_y}{\bar{E}_s I} + \frac{2\eta_{s,xx}^{(1)}}{\pi \bar{E}_s I} T
\]
\[
\bar{\phi} = \frac{4\eta_{s,xx}^{(1)}}{\pi \bar{G}_{xx} J} M_y + \left(1 + \frac{8}{\pi^2 - 1}\right) \eta_{s,xx}^{(1)} \eta_{s,xx} \frac{T}{\bar{G}_{xx} J}
\]

In deriving the above relations we have used \(T = 2\pi R^2 \tau_0\), \(J = 2I = 2\pi R^3 h\), and the symmetry relation \(\eta_{s,xx}/E_x = \eta_{s,xx}/G_{xx}\). The shear stresses due to the transverse force \(F_z\) can be obtained from [3] using \(\Delta E_x = 0\) and \(E_x^{(1)} = E_x^{(2)} = E_x\):

\[
\tau_{ss}(\theta) = \tau_{ss}(0) + \frac{V_z R^2}{I} (\cos \theta - 1)
\]

Note that the shear stress expression is the same for both top and bottom halves of the tube. The constant \(\tau_{ss}(0)\) can be evaluated from the fact that the moment of the shear stresses about the center should vanish as the force \(F_z\) is applied at the center. The final expression for shear stress takes the form
\[ \tau_{ss}(\theta) = \frac{V R^2}{I} \cos \theta = \frac{V R}{I}y \]  

(17)

Thus the shear stress distribution will be symmetric about the z-axis such that \( \tau_{ss}(y) = \tau_{ss}(-y) \). Thus the shear flow will be in the counter clockwise direction on the right half of the tube \((y>0)\) and in the clockwise direction in the left half \((y<0)\). The shear stresses will not contribute to rotation about the x-axis as the material is also symmetric about the z-axis.

3.2 Shear Center

Consider a cantilevered tube clamped at \( x=0 \). First we will consider the case where the tube is subjected to a force \( F_z \) at the tip \( x=L \). The force is such that the line of action is through the center of the tube. The bending moment distribution is given by \( M_y(x) = -F_z(L-x) \). The tip rotation about the x-axis can be obtained from the second of equation (15):

\[
\frac{d \psi_x}{dx} = \tilde{\phi} = \frac{4\eta_{ss,s}^{(1)}}{\pi G_{ss} J} F_z(x-L)
\]

(18)

Integrating the above equation and noting \( \psi_x(0)=0 \) we obtain the tip rotation \( \psi_x^T \) due to the transverse force \( F_z \) as

\[
\psi_x^T = \frac{-2\eta_{ss,s}^{(1)}}{\pi G_{ss} J} F_z L^2
\]

(19)

From (15) the rotation \( \psi_x^T \) due to torque \( T \) can be derived as

\[
\psi_x^T = \left(1 + \left( \frac{8}{\pi^2} - 1 \right) \eta_{ss,s}^{(1)} \eta_{ss,s}^{(1)} \right) \frac{TL}{G_{ss} J}
\]

(20)

The location of the shear center can be derived as follows. Let the shear center distance – distance of the shear center from the tube axis – be denoted by \( e_y \) (Figure 5). That is, if the transverse force \( F_z \) is applied at the shear center it would not produce any twisting of the tube, as the torque produced by the eccentric loading, \( F_z e_y \), would cause an angle of twist equal in magnitude but opposite in direction to that produced by the force \( F_z \). Then,

\[
\psi_x^T = -\frac{\psi_x^T}{T} (F_z e_y) \Rightarrow e_y = -\left( \frac{\psi_x^T / F_z}{\psi_x^T / T} \right)
\]

(21)

Substituting from (19) and (20) in the above equation, the shear center distance can be written in a non-dimensional form as

\[
e_y = -\frac{(\psi_x^T / F_z)}{(\psi_x^T / T) L} = -\frac{2\eta_{ss,s}^{(1)}}{\pi \left(1 + \left( \frac{8}{\pi^2} - 1 \right) \eta_{ss,s}^{(1)} \eta_{ss,s}^{(1)} \right) L}
\]

(22)
From (14) we note that the bending moment $M_z$ due to a transverse force $F_y$ will not cause any twisting. Hence the shear center will be on the $y$-axis at a distance $e_y$ from the center of the tube.

![Diagram of shear center for a tube made of an anisotropic material with different orientation of the principal material axis in the top and bottom halves of the tube as shown in Figure 3.]

We have already shown that the transverse shear stresses due to the force $F_z$ do not contribute to the rotation due to symmetry of the cross section about the $z$-axis. Thus we note the eccentricity of the shear center in the present case is due to the extension-shear coupling of the material. In homogeneous beams the eccentricity of the shear center is due to asymmetry of the cross section, *e.g.*, a C-channel. That is why the shear center location in the present case is independent of the radius $R$, but proportional to the tube length $L$ and the coefficients of mutual influence $\eta$.

### 3.3 Laminated Composite Tubes

In most applications the tube has to be made of multiple plies with different fiber orientations to achieve a given bending stiffness, torsional stiffness and desired bend-twist coupling. In that case the laminated tube can be modeled as a tube with an equivalent anisotropic material. The compliance matrix $[\bar{S}]$ (see equation (4) above) of such an equivalent material can be obtained from the in-plane stiffness $[A]$ of the laminate as follows [5]:

$$
[S_{eq}]=h[A]^{-1}
$$

where $h$ is the laminate thickness. It should be noted that the above idealization is valid only for thin-walled tubes such that $h/R<<1$.

### 4 FINITE ELEMENT ANALYSIS

The commercial finite element software Abaqus was used for computational analysis of aforementioned tubes. Eight-node doubly curved thick shell elements (S8R Element) were used to model the tubes. This element has six DOFs per node. About 30 elements were used along the circumference of the tube. The number of elements in the length direction was such that the aspect ratio of elements is approximately equal to unity. That is, the elements were almost square in shape. In the examples considered the tube was fixed at one end by setting all degrees of freedom equal to
zero. At the free end, a reference node was created at the center of the tube and it was connected to the circumferential nodes using multipoint constraints. The transverse force and the couple were applied at the reference node.

![Figure 6. (a) FE mesh of the composite tube; (b) deformed shape after subjected to a torque at the tip. Note that the circumferential expansion of the tube is exaggerated in the figure.](image)

5 RESULTS AND DISCUSSION

All examples below are concerned with a cantilevered tube of length \( L \), mean radius \( R=10 \) mm and wall thickness \( h=2 \) mm. The tapered tube’s radius varies from 5 mm at the fixed end to 15 mm at the free end.

5.1 Example 1a- One Anisotropic Material

The laminate configuration or lay-up is denoted by \([20^*]\). The superscript* denotes that for the top half of the tube \( \alpha = +20^\circ \) and for the bottom half \( \alpha = -20^\circ \) (see Figure 3). The elastic constants are: \( E_1=138 \) GPa; \( E_2=9 \) GPa; \( G_{12}=6.9 \) GPa and \( v_{12} = 0.3 \). Tubes of two different lengths, 200 and 300 mm, were considered to demonstrate the length-dependence of shear center location. Two different forces were considered: a transverse tip force \( F_z \) applied at the center of the tube and a torque \( T \). In TABLE 1 the FE results are compared with that obtained from the analytical method. It can be noted that the agreement for deflection, rotation, and shear center distance are excellent. Furthermore, the ratio \( e_z/L \) does not change at all for the two different lengths of the tube.

5.2 Example 1b - Laminated Tube

In this example we consider a laminated tube. The lay-up is denoted by $[0/(20^\circ)_{2}/0]^T$. Explicitly stated, the top half of the tube has a lay-up given by $[0/(20^\circ)_{2}/0]^T$ and the bottom half $[0/(-20^\circ)_{2}/0]^T$. The elastic constants of the ply material were same as in Example 1A. The forces applied are similar to the previous example. The results are presented in TABLE II. Again one notices that the agreement between the analytical results and FEA results is excellent. The shear center distance specified by $e_y/L$ is smaller, i.e., the shear center is closer to the tube center, for the laminated tube compared to the 20-degree lamina in Example 1A, because the laminate includes some 0-degree plies. The reduction in the effective coefficient of mutual influence due to the presence of 0-degree plies reduces the shear center distance also.

5.4 Experimental Validation
The composite tubes were designed with the chevron pattern detailed above. An example of the lay-up is shown in Figure 7. The 0° plies on the inner and outer layers were added to provide structural integrity to the lay-up. The experimental set-up is shown in Figure 8 and Figure 9. A special apparatus was constructed to load the tip with an adjustable torque, Figure 10. Digital image correlation (DIC) was used to measure tip rotation and deflection. From these measurements shear center values were determined as the length of moment arm that results in bending absent twisting. Repeating this process for different shaft lengths and orientations allowed for a final $e/L$ measurement for the given design. Steps of the experiment were repeated to reduce the various uncertainties in these measurements. The experiment utilized three dimensional DIC, a vice to simulate the rigid boundary of a cantilever, an adjustable moment arm on which to load the specimen, and the means to manufacture composite shaft specimens. The results were compared against finite element and analytical predictions. The final average experimental $e/L$ for all four shafts was 8% higher than what the analytical method and FEA predicted, [1].

Figure 7. Schematic of lay-up

Figure 8. Schematic of the experimental set-up
The final results averaged across multiple tests on four nominally identical shafts is shown in TABLE III. COMPARISON OF TECHNIQUES TABLE III.
6 SUMMARY

An analytical model is presented for thin walled composite tubes subjected to a combination of bending and torsion. The methods are applied to a novel design of composite tubes with lay-ups in the top and bottom halves of the cross section. Due to the difference in lay-ups, the tube exhibits strong bend-twist coupling and the shear center is at a distance from the geometric center of the tube. The shear center distance is independent of the tube radius but proportional to the length of the tube and the effective coefficient of mutual influence of the laminates. The results are verified using finite element analysis and experimental testing. The excellent agreement in results suggests that the assumptions made in the analytical model are reasonable and correct.
