

EVALUATING THE EQUATION $\text{SQRT}[(x+R)^2-N]=\text{INTEGER}$

Several years ago we found that any semi-prime $N=pq$ has its prime components given by-

$$[p,q]=(x+R) \mp \text{sqrt}[(x+R)^2 - N]$$

, where the radical-

$$F(x)=\text{sqrt}[(x+R)^2-N]=\text{sqrt}(x^2+2xR+(R^2-N)) \text{ must be an integer.}$$

Once $F(x)$ has been found the prime components become-

$$p=x+R-F(x) \quad \text{and} \quad q=(x+R)+F(x) \quad .$$

We wish in this note to examine the properties of the Diophantine Equation $F(x)=\text{int}$.

The first thing we notice is that the dominant term in the second square root is $2xR$ and not x^2 or (R^2-N) . R is typically much larger than x . So we can set $x=aR$ with a guess for 'a' in the range $0 < a \ll 1$. A graph of $F(x)$ will give a clue as to which 'a' to choose as a search starting point.

To find the exact values of x and $F(x)$ we apply the following computer search procedure-

```
for x from aR to aR+c do({x,sqrt[(x+R)^2-N]})od;
```

For smaller semi-primes we can set 'a' to zero and run things for 'c' trials.

Let us use this computer approach for several different semi-primes. We begin with the semi-prime-

$$N= 3431 \quad \text{where } R=59$$

Starting the search with 'a'=0, we get the first three terms to read-

x	F(x)
0	sqrt(50)
1	13
2	sqrt(290)

So we get an integer $F(x) = 13$ at $x=1$. This means –

$$p = 1 + 59 - 13 = 47 \quad \text{and} \quad q = 1 + 59 + 13 = 73.$$

Next take the six digit long semi-prime –

$$N = 455839 \quad \text{for which} \quad R = 676.$$

Using just five trials, starting with $x=0$, we get-

$$x = 4 \quad \text{producing} \quad F(x) = \sqrt{(4 + 676)^2 - N} = 81$$

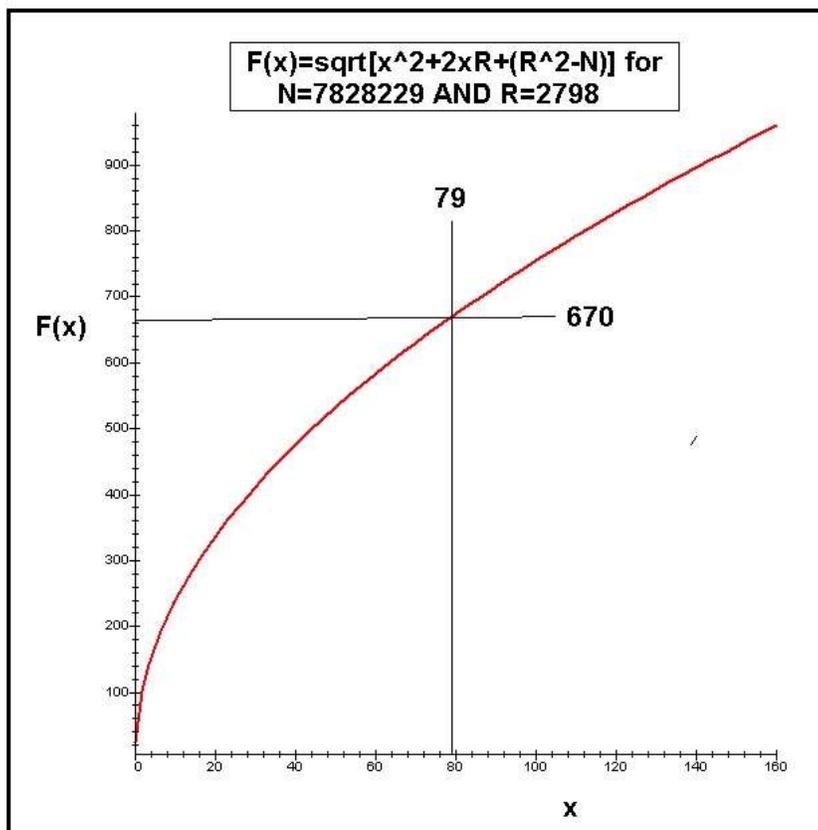

So the prime components become-

$$p = 4 + 676 - 81 = 599 \quad \text{and} \quad q = 4 + 676 + 81 = 761$$

As a third case consider the seven digit long semi-prime-

$$N = 7828229 \quad \text{where} \quad R = 2798$$

Its $F(x)$ plot in the range $0 < x < 160$ has the parabolic like shape shown-

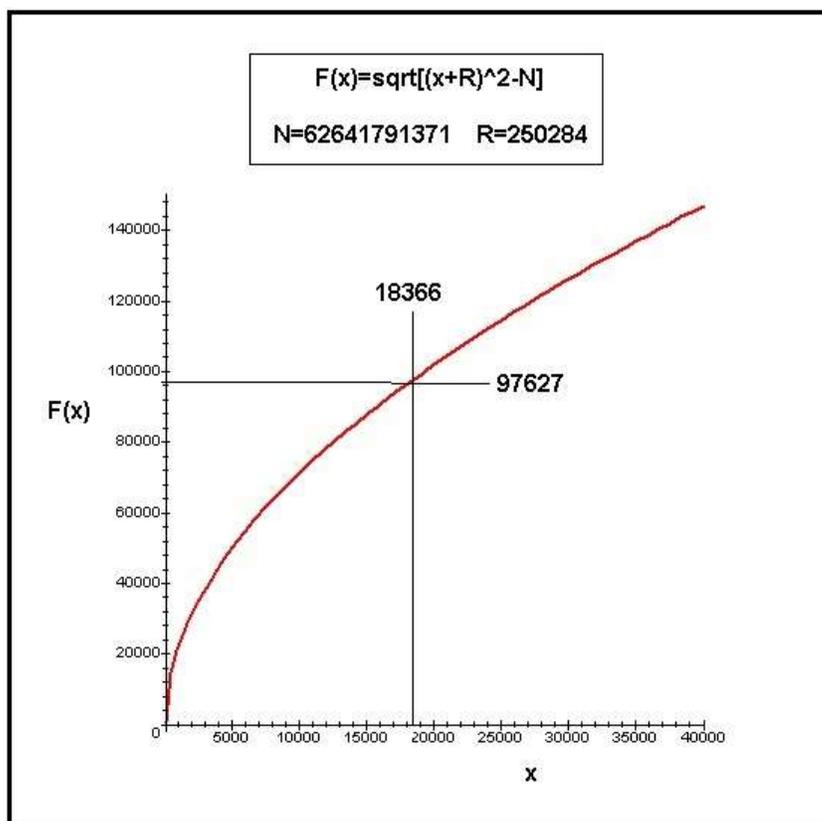

Our computer program, run over the range $x=0$ to $x=160$, shows that the integer solution is here $x=79$ with $F(x)=670$. We see this occurs along the $F(x)$ curve just slightly to the left of where $F(x)$ becomes asymptotic. This suggest one can carry out future searches with still larger N s by looking at an x just slightly to the left of the asymptotic form of $F(x)$.

Let us demonstrate the procedure for the eleven digit long semi-prime-

$$N=62641791371 \quad \text{where} \quad R=250284$$

The $F(x)$ curve drawn over the range $0 < x < 40,000$ looks as follows-

So carrying out a computer search near $x=18000$ produces the integer solution $[x, F(x)] = [18366, 97627]$. From it we have the prime factors-

$$p = x + R - 97627 = 171023 \quad \text{and} \quad q = x + R + 97627 = 366277$$

Taking the product of p and q returns the original semi-prime N .

What is clear from the above examples is that the number of trials increases dramatically as N gets larger if one starts the search at $x=0$. In that situation one should try a larger $x = aR_s$ as a starting point and run things out to c . The starting point value of x is suggested by looking at the parabolic shaped $F(x)$ curve slightly to the left of its asymptote for the specified N under consideration.
