

EVALUATION OF THE NUMBER-FRACTION FOR ANY INTEGER

About a decade ago (<https://mae.ufl.edu/~uhk/NUMBER-FRACTION.pdf>) we came up with a new point-function which represents the ratio of all divisors of any integer minus the integer and one all divided by N. Mathematically one has-

$$f(N) = \frac{[\sigma(N) - N - 1]}{N}$$

, where $\sigma(N)$ is the sigma function of Number Theory. This function, which we have called the number-fraction $f(N)$, has the interesting property that it vanishes whenever N is a prime number. It exhibits rather wild fluctuations ranging from zero to, what we will show below, infinity. A plot of $f(N)$ between $N=3$ and $N=61$ follows-

The average value in this range lies a little below unity with the primes clearly shown at $f(N)=0$. We call all those values of $f(N)$ greater than one super-composites. We have found numerous applications for this function including its role in twin-primes, the construction of a general prime number function, and its role in factoring large semi-primes. It is our purpose here to determine the number fraction $f(N)$ for any chosen integer N using both analytical approaches and computer evaluations.

We begin with finding all values for $f(p^n)$, where p is any prime number. We have-

$$\begin{aligned}
f(p) &= 0 \\
f(p^2) &= 1/p \\
f(p^3) &= (1+p)/p^2 \\
f(p^4) &= (1+p+p^2)/p^3
\end{aligned}$$

so that-

$$f(p^n) = 1/[p^{(n-1)}] \sum_{k=0}^{n-2} p^k$$

Summing this last finite geometric series produces-

$$f(p^n) = \frac{1}{(p-1)} \left[1 - \frac{1}{p^{n-1}} \right]$$

Thus $f(p^n)$ approaches the finite value $1/(p-1)$ as n goes to infinity.

We have $f(625) = f(5^4) = [1 - 1/125]/4 = 31/125 = 0.272\dots$. One can rewrite $f(p^2) = 1$ as a new prime number formula-

Any number satisfying $J(N) = N/[\sigma(N^2) - N^2 - 1] = 1/[Nf(N^2)] = 1$
is a prime number

To test this formula consider the number $N=2861$. It has-

$$J(N) = 2861 / (8188183 - 8185322) = 1$$

So 2861 is a prime. For composite numbers, $J(N)$ will lie in the range $0 < J(N) < 1$. For primes we have $J(N) = 1$.

If one has the semi-prime $N=pq$, its unique number-fraction is $f(p,q) = (p+q)/pq$. This lies close to zero as the primes p and q get large.

To calculate $f(N)$ for any integer N up to about twenty digit length first go to-

<http://www.javascripter.net/math/calculators/divisorscalculator.htm>

to find $\sigma(N)$ and then use $f(N) = [\sigma(N) - N - 1]/N$.

So $N=123456789$ has $\sigma(N) = 178422816$ yielding $f(N) = 0.44522\dots$

We find local maxima in the range up to 400 at $N=$

$$60 = 2^2 \times 3 \times 5 \quad 180 = 2^2 \times 3^2 \times 5 \quad 360 = 2^3 \times 3^2 \times 5$$

Note that these numbers have the peculiar exponential form with the lowest prime components having the highest prime power. This suggests a new point function falling into the super-composite range having the forms-

$$2^3 \times 3^2 = 72 \quad , \quad 2^5 \times 3^3 \times 5^2 = 21600 \quad \text{etc.}$$

So the prime components increase one prime at a time while their powers drop one prime at a time. This new rapidly growing point function generalizes to-

$$F = \prod_{k=1}^m \text{ithprime}(k)^{\text{ithprime}(m+1-k)}$$

The ithprime values are found, for example, at-

<https://primes.utm.edu/nthprime/index.php#nth.htmlAs>

As an example, we have for m=4 the large number-

$$F = 2^7 \times 3^5 \times 5^3 \times 7^2 = 190512000$$

This has –

$$\sigma(F) = 825355440$$

So that the number fraction becomes-

$$f(F) = (825355440 - 190512000 - 1) / 190512000 = 3.33230158..$$

This f(F) lies clearly in the super-composite range. We have also evaluated f(F) for m= 10, 25, 50, 100, and 150. In these cases we find-

$$f(10) = 5.330946.. \quad f(25) = 7.311348.. \quad f(50) = 8.800312..$$

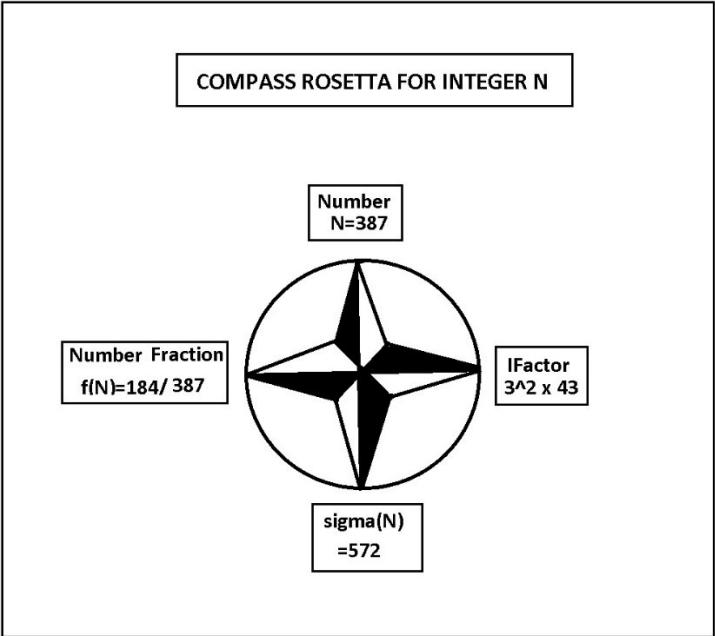

$$f(100) = 10.267620.. \quad \text{and} \quad f(150) = 11.115341..$$

Although my PC had no problems in finding f(F) for m less than 100, it did slow down to a four minute crawl finding the f(150) value of 11.115. In examining all of the above f(m) numbers, it seems that there is no limit to the super-composite value meaning the function –

$$\lim_{m \rightarrow \infty} \text{ has } f(F) \text{ infinite}$$

It will, however, reach infinity very slowly somewhat similar to what happens with the harmonic series.

In conclusion we can say that the number-fraction can be evaluated exactly for all Ns less than 20 digit length using my PC. For Ns greater than this value a new analytic function F(m) can be used to calculate a new supercomposites f(F) out to infinite value. As a final thought, we can combine N-ifactor-sigma(N)-f(N) into the following four pointed compass rosetta-
